PREFACE

Dear colleagues,

In your hands is the Book of Abstracts of the 12th International Scientific Agricultural Symposium "AGROSYM 2021", which I hope you will find useful in your work. As many as 700 contributions have been accepted for the Book of Abstracts. The themes of AGROSYM 2021 cover all branches of agriculture and are divided into seven sessions: 1) Plant production, 2) Plant protection and food safety, 3) Organic agriculture, 4) Environmental protection and natural resources management, 5) Animal husbandry, 6) Rural development and agro-economy, and 7) Forestry and agroforestry.

The multi-functionality of agriculture (viz. crop production, animal production and fisheries) and the central role it plays in food production, food security, rural development, bio-economy (e.g. production of fibres and raw materials for industries) and green economy (e.g. production of biofuels) determine its importance in all countries; especially nowadays, with the second year of the COVID-19 pandemic.

Many scholars and practitioners argue that technology will increase production and feed more people while reducing the variability as well as the environmental impacts of agricultural production. Technology has been particularly important for improving production in non-tree crops such as maize, rice, soybean, wheat and cotton. Because trees have longer cycles, they take longer to improve through traditional breeding programs. New techniques of plant breeding can improve productivity further, but there is a lively academic debate about their pros and cons.

While the focus has been in the past on the production side (cf. productivity, efficiency), more and more attention is nowadays paid to the consumption side as well as the intermediate stages (e.g. processing, distribution) of the food chain thus moving towards a 'farm to fork' approach. Globally, consumers are sending clearer signals than ever before about what they want on their tables i.e. higher quality as well as healthier, safer, and tastier products. Therefore, most companies in the food industry are currently exploring different ways to ensure that they have more control over the production processes for agricultural commodities as well as final products quality. Changes in investment strategy also have the potential to reduce the environmental and social costs of agriculture. It is now apparent to most investors that companies that pay more attention to sustainability and social responsibility, even with the same financial rating, will have better returns both in the short term and over time.

Agri-food systems have been central in the global debate on sustainable development and the achievement of the Sustainable Development Goals (SDGs) as shown by the recent United Nations' Food Systems Summit held in September 2021 in New York. Indeed, agri-food systems are at the center of various global challenges such as climate change, poverty, vulnerability, food insecurity, biodiversity loss, resource scarcity and ecosystem degradation. In this context, one of the goals of the sustainable agriculture movement is to create farming systems that mitigate or eliminate environmental harms associated with industrial agriculture.

Many thanks to all the authors, reviewers and colleagues for their help in editing the Book of Abstracts. Special thanks go to all co-organizers and partners for their unselfish collaboration and comprehensive support.

Abstract

Worldwide, agricultural productivity is exposed to increasing constraints in the form of abiotic stresses such as salinity which affects plant growth and development causing yields loss. Previous studies suggest that seed priming improves stand establishment under optimal and stressful environment, given that seed priming might improve seed germination and initial development by altering seed vigour. This research aimed to define whether various seed priming treatments could be a feasible strategy to improve garden pea (*Pisum sativum* L.) resistance to abiotic stress, namely to salinity. Four garden pea cultivars obtained from the Department for Vegetable and Alternative Crops, Institute of Field and Vegetable Crops, Novi Sad, Serbia were included. Seeds of the tested pea cultivars were primed in distilled water (hydropriming), -0.5 MPa polyethylene glycol PEG 6000 solution, and 0.5% KNO₃ solution for 24 hours at 25°C in dark. Non-primed seeds were taken as control. Seeds were submitted to germination test, using 120 mM NaCl to simulate salt stress. The energy of germination, germination, abnormal seedlings, shoot and root length, fresh and dry shoot and root biomass, and seedling vigour index were estimated. The results showed significant differences among garden pea cultivars and seed priming treatments for the assessed traits. Besides, the results also showed a positive effect of the tested priming treatments on the germination and initial growth of garden pea cultivars grown under saline conditions, but for hydropriming to a lesser extent than osmopriming. Findings point out that seed priming with KNO₃ and PEG solution could be considered as an efficient method to improve garden pea seed germination and initial growth under saline conditions.

Keywords: *garden pea, initial plant development, saline stress, seed priming, seed quality.*
