#### Abstract

Rhizoctonia spp. comprise soil-borne fungi widely distributed in temperate climate worldwide which are annually causing significant yield loses to a range of cultivated plants. A species status of *Rhizoctonia spp.* has not yet been established and the isolates are classified based on nuclei status as multinucleate and binucleate Rhizoctonia spp., and further divided into 13 anastomosis groups (AG) (AG-1-13) of multinucleate Rhizoctonia and 23 AG (AG-A-W) of binucleate Rhizoctonia. In this paper we are reporting morphological and molecular features of binucleate Rhizoctonia spp. AG-A causing black root rot on strawberry and multinucleate R. solani AG-2-2 causing root and crown rot of sugar beet. During 2015 and 2016 at several strawberry and sugar beet producing areas, plants expressing prominent root and crown necrosis and rot have been observed with disease incidence estimated at 20-30%. At two localities, in the vicinity of Belgrade (City of Belgrade District) and Vašica locality (Srem District), symptomatic strawberry and sugar beet plants were sampled and 12 and 8 Rhizoctonia-like isolates have been recovered, respectively. As exhibiting uniform morphological features, two representative isolates originating from strawberry and sugar beet (101-16 and 270-15) were selected and identified. Pathogenicity of representative isolates was confirmed in artificial inoculations of strawberry runners or sugar beet seedlings, respectively, followed by a successful reisolation. The isolates were identified based on hyphal branching pattern, nuclear status (binucleate isolate from strawberry and multinucleate from sugar beet) and conventional AG pairing with known tester isolates. The identification was confirmed by sequencing of ITS region of rDNA of isolates 101-16 and 270-15 (GenBank MH517393 and MK123309, from strawberry and sugar

beet, respectively). Identification of multinucleate R. solani AG-2-2 was also confirmed using sensitive and specific real-time PCR protocol.
